Method and Apparatus for describing sound sources

The invention relates to a method and to an apparatus for
5 describing sound sources, especially for sound sources
encoded as audio objects according to the MPEG-4 Audio stan-
dard.

10 Background

The MPEG-4 Audio standard as defined in ISO/IEC 14496-3 and
14496-1 facilitates a wide variety of applications by sup-
porting the representation of audio objects. For the combi-
15 nation of the audio objects additional information - the so-
called scene description - determines the placement in space
and time and is transmitted together with the coded audio
objects.

For playback the audio objects are decoded separately and
20 composed using the scene description in order to prepare a
single soundtrack, which is then played to the listener.

For efficiency, the MPEG-4 Systems standard ISO/IEC 14496-
1 defines a way to encode the scene description in a binary
25 representation, the so-called Binary Format for Scene De-
scription (BIFS). Correspondingly, audio scenes are de-
scribed using so-called AudioBIFS.

A scene description is structured hierarchically and can be
30 represented as a graph, wherein leaf-nodes of the graph form
the separate objects and the other nodes describes the proc-
essing, e.g. positioning, scaling, effects etc.. The appear-
ance and behavior of the separate objects can be controlled
using parameters within the scene description nodes.

35

Invention

The invention is based on the recognition of the following fact. Currently the MPEG-4 Audio standard cannot describe
5 sound sources that have a certain dimension, like a choir, orchestra, sea or rain but only a point source, e.g. a flying insect, or a single instrument. According to listening tests wideness of sound sources is clearly audible, whereby more complicate descriptions like the shape of the audio
10 object is not necessary.

Therefore, a problem to be solved by the invention is to allow the description of the wideness of sound sources that have a certain dimension in a simple and backwards
15 compatible way.

This problem is solved by the method disclosed in claim 1 and the corresponding apparatus in claim 4.

20 In principle, the inventive method allows to describe sound sources, which are encoded as separate audio objects. The arrangement of the sound sources in a sound scene is described by a scene description. For playback the audio objects are decoded separately and a single soundtrack is composed from the decoded audio objects using said scene description.
25 For describing the wideness of a sound source an audio spatial diffuseness node is defined within the scene description.

30 Advantageous additional embodiments of the invention are disclosed in the respective dependent claims.

Drawings

35

Exemplary embodiments of the invention are described with reference to the accompanying drawings, which show in

Fig. 1 the illustration of the functionality of the
AudioSpatialDiffuseness mode;

5 Fig. 2 an Audio Scene for a Line Sound Source.

Exemplary embodiments

10 Figure 1 shows an illustration of the functionality of the
inventive AudioSpatialDiffuseness node.

This AudioSpatialDiffuseness node will have a children field
as input and will produce the same number of channels (num-
15 Chan) as output. Branches that are connected to an upper
level branch are called children in MPEG-4 terms. It can be
inserted in each branch of the audio subtree, without chang-
ing any other node.

20 A diffuseSelection field will allow the scene author to con-
trol the diffuseness algorithms, so that each AudioSpa-
tialDiffuseness node will produce a different output. In
practice a diffuseness node will virtual produce N different
signals, but only one real signal is passed through to the
25 output of the node, signaled by the diffuseSelect field.
Other fields like a decorrelation strength (decorrStrength) etc.
could be added to the node, if required.

```

AudioSpatialDiffuseness {
    eventin    MFNode addChildren
    eventin    MFNode removeChildren
5   exposedField    MFNode children          [ ]
    exposedField    SFInt32 diffuseSelect      1
    exposedField    SFInt32 decorreStrength    1
    field          SFInt32 numChan              1
    field          MFInt32 phaseGroup           [ ]
10  }

```

Table 1: Semantics of the proposed AudioSpatialDiffuseness Node

15 In the case of numChan greater than one each channel should be diffused separately.

Figure 2 depicts an Audio Scene for a Line Sound Source. By using this proposal the scene author has to decide how many and at which position the decorrelated multiple point sound sources will be located. The advantage is, that the content author has much more control over the shape effect. He can also use intensity and direction of each point source as well as using the AudioDelay and AudioEffects node for cer-

20

25 tain Sound nodes to manipulate the effect.

It is still possible for the renderer to reduce the computational power by passing the scene tree to look for identical AudioSources.

Claims

1. Method for describing sound sources, which are encoded as
separate audio objects, wherein the arrangement of the
5 sound sources in a sound scene is described by a scene
description, and wherein for playback the audio objects
are decoded separately and a single soundtrack is com-
posed from the decoded audio objects using said scene de-
scription, **characterized by** an audio diffuseness node
10 which is defined within the scene description for
describing the wideness of a sound source.
2. Method according to claim 1, wherein a diffuse selection
field will allow the scene author to control the
15 diffuseness algorithms.
3. Method according to claim 1 or 2, wherein a decorrelation
strength field will allow author to control the strenght
of the decorrelation.
20
4. Apparatus for performing a method according to any of
claims 1 to 3.

Abstract

The MPEG-4 Audio standard as defined in ISO/IEC 14496-1 and -3 facilitates a wide variety of applications by supporting the representation of audio objects. For the combination of the audio objects additional information - the so-called scene description - determines the placement in space and time and is transmitted together with the coded audio objects.

For playback the audio objects are decoded separately and composed using the scene description in order to prepare a single soundtrack, which is then played to the listener. A scene description is structured hierarchically and can be represented as a graph, wherein nodes of the graph form the separate objects. The appearance and behaviour of the separate objects can be controlled using parameters within the scene description nodes. For describing the wideness of a sound source an audio diffuseness node is defined within the scene description.
